

## An illustration of a hand holding a fan of playing cards (Ace of Spades, King of Hearts, Queen of Hearts, Jack of Hearts, and Ace of Diamonds) over a red roulette table. The table features a black wheel and various betting areas. Other items on the table include a white card with a black club symbol, a red roulette chip, a black roulette chip, a black die, and a white card with a red heart symbol. The word 'ker' is visible in the bottom left corner, likely part of 'Poker'.

# What is Poker?

- Poker is a card game where players are dealt cards, and bet across multiple rounds based on the strength of their hand with the goal to win the most amount of money.
- Poker has many variants, including No Limit Texas Hold' Em (one of the most popular), Pot Limit Omaha (PLO), Limit Texas Hold' Em, as well as many others.
- There have been many attempts to solve poker. In 2007, the Counterfactual Regret Minimization (CFR) algorithm was published [1], which has proven to be the standard algorithm for solving games like Poker. More recently, researchers at CMU built Libratus [2], which applied the CFR algorithm (along with other AI techniques) to try to build the best heads-up poker bot in existence.
- Traditional algorithms like MCTS perform poorly for creating optimal strategy.

# Basic Poker Strategy

this matter?

---

# Understanding Mathematically Optimal Poker

## Problem

If we always bet when we have a good hand and fold when we have a bad hand, it will be too easy for our opponent to realize and outplay us!

## Nash Equilibrium

$$u_i(s_i^*, s_{-i}^*) \geq u_i(s_i, s_{-i}^*) \text{ for all } s_i \in S_i$$

## Solution

Value hands (made hands) must be equally balanced out with bluff hands (hands where we bet to try to get opponents to fold)

# A Simple Probabilistic Strategy: Push/Fold against SB Open

- Before the flop, we are either going to fold, or go all in with 10BB against our opponent's 2BB open.
- The other player can either call this all in, or fold.
- Because both players have to put in “blinds,” there is a reward if the opponent folds.
  - Likewise, if we fold, we lose our blind.
- No post flop play. This massively simplifies the game, and the number of decisions we have to make.

# Reward Matrix

Actions	Push	Fold
Win (Opponent Call)	+10	-1
Win (Opponent Fold)	+3	
Lose	-10	

# Approach: CFR-Based Analysis

## Counterfactual Regret Minimization

### CFR Algorithm Key Components:

- Starts with a uniform strategy
- At each point in the game tree, the algorithm tracks the current regret — how much better we are performing by playing the current strategy rather than the probabilistic strategy
- Computes counterfactual heuristic as the product of reaching a game state (with the current player and opponent in mind) and the expected value of all of the possible outcomes of that state

# Approach 1: CFR-Based Analysis

## Counterfactual Regret Minimization

These three equations govern how the CFR algorithm improves the strategy over time.

CFR, The Math [1].

$$u_i(\sigma, I) = \frac{\sum_{h \in I, h' \in Z} \pi_{-i}^\sigma(h) \pi^\sigma(h, h') u_i(h')}{\pi_{-i}^\sigma(I)}$$

$$R_i^T(I, a) = \frac{1}{T} \sum_{t=1}^T \pi_{-i}^{\sigma^t}(I) (u_i(\sigma^t|_{I \rightarrow a}, I) - u_i(\sigma^t, I))$$

$$\sigma_i^{T+1}(I)(a) = \begin{cases} \frac{R_i^{T,+}(I, a)}{\sum_{a \in A(I)} R_i^{T,+}(I, a)} & \text{if } \sum_{a \in A(I)} R_i^{T,+}(I, a) > 0 \\ \frac{1}{|A(I)|} & \text{otherwise.} \end{cases}$$

# Why CFR?

- We have learned many algorithms for solving problems involving uncertainty in class — so why CFR?
- MCTS and Minimax work very poorly because of the uncertainty involved in the game. A worse hand preflop can still win a fair amount of the time at the end.
- Poker is typically not considered a game where a Markov model is applicable because it is very history dependent.

A possible poker game tree [4]

# A Brief Discussion about Stack Depth

- The Small Blind (SB) and Big Blinds (BB) are the amount of money one has to put into the hand without seeing their cards
- We have said that the Small Blind is going to open to 3BB with any hand, and are asking the question of which hands are we shoving with.
- We expect that as the **stack sizes get larger**, we are shoving a **smaller** proportion of our hands because we have more money relative to the money in the pot.

100BB	225.6 bb/100	148.1 bb/100

# Data from Training

Strategy EV over Time (100BB)

# Results Discussion

- Training poker solvers is **really** difficult. The game tree can become huge extremely quickly, and simulating poker hands can get **very** slow.
- Results ended up looking somewhat expected, particularly for the 50BB and 100BB strategy. The 10BB solver strategy is willing to shove/defend which a much larger proportion of hands than I expected.
- These solver strategies are **crushing** random and uniform strategies
